Visual Analysis of Economic and Human Development

Power BI Data Analytics Project

Country comparisons, development indicators, and natural-resource context

Purpose. This companion document presents the ten dashboard views from the project and briefly explains the analytical question each view addresses. The screenshots are reproduced from the supplied Power BI visuals. Interpretations below are based on the indicators and comparisons visible in those screenshots; they should not be read as causal estimates.

Top-performing countries across selected indicators

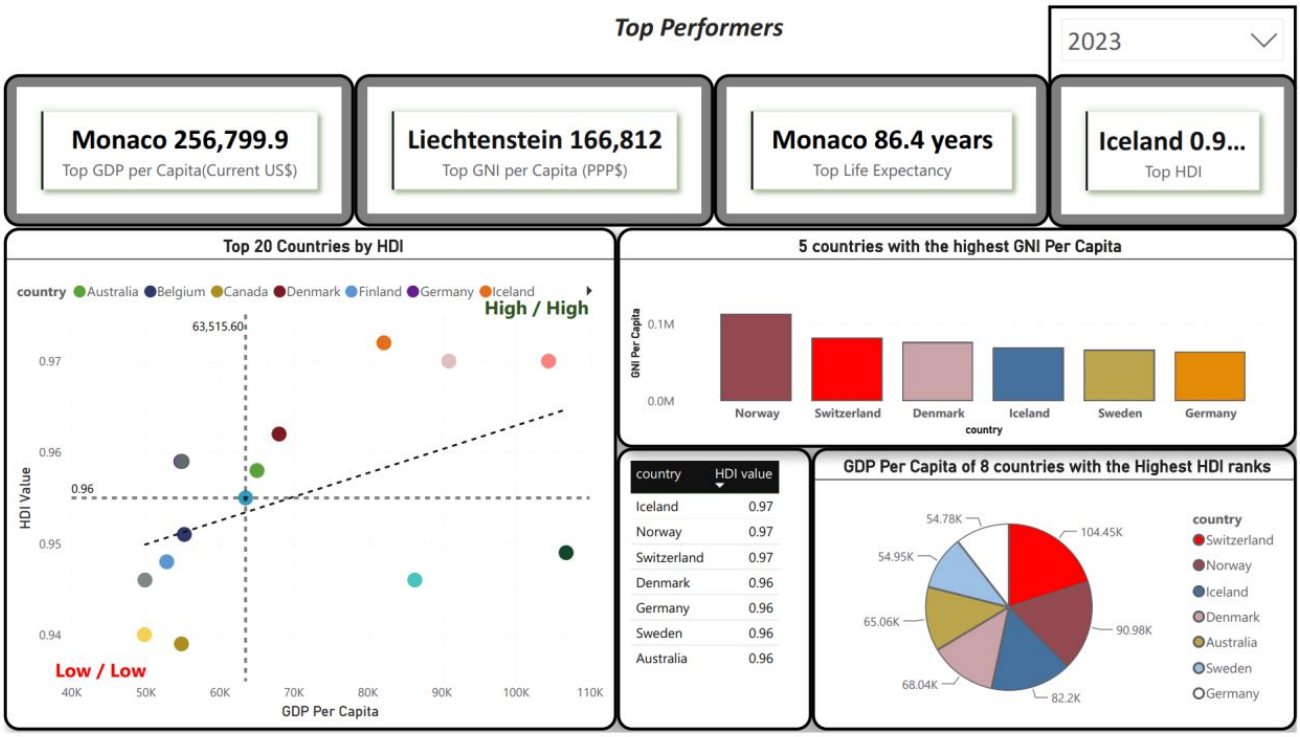

Figure 1: Top performers: GDP per capita, GNI per capita, life expectancy, HDI, and related comparisons.

This overview highlights countries that rank highly on selected measures of economic output, income, longevity, and human development. The dashboard deliberately places several indicators side by side: a country leading in one measure does not necessarily lead in every other measure. The scatter plot and ranked comparisons help distinguish very high income levels from broader human-development outcomes.

The view is useful for identifying benchmarks, but rankings depend on the selected year, indicator definitions, and country coverage. The figures shown in the dashboard should therefore be interpreted as indicator-specific comparisons rather than a single definitive ranking of national well-being.

Countries with the lowest values on selected indicators

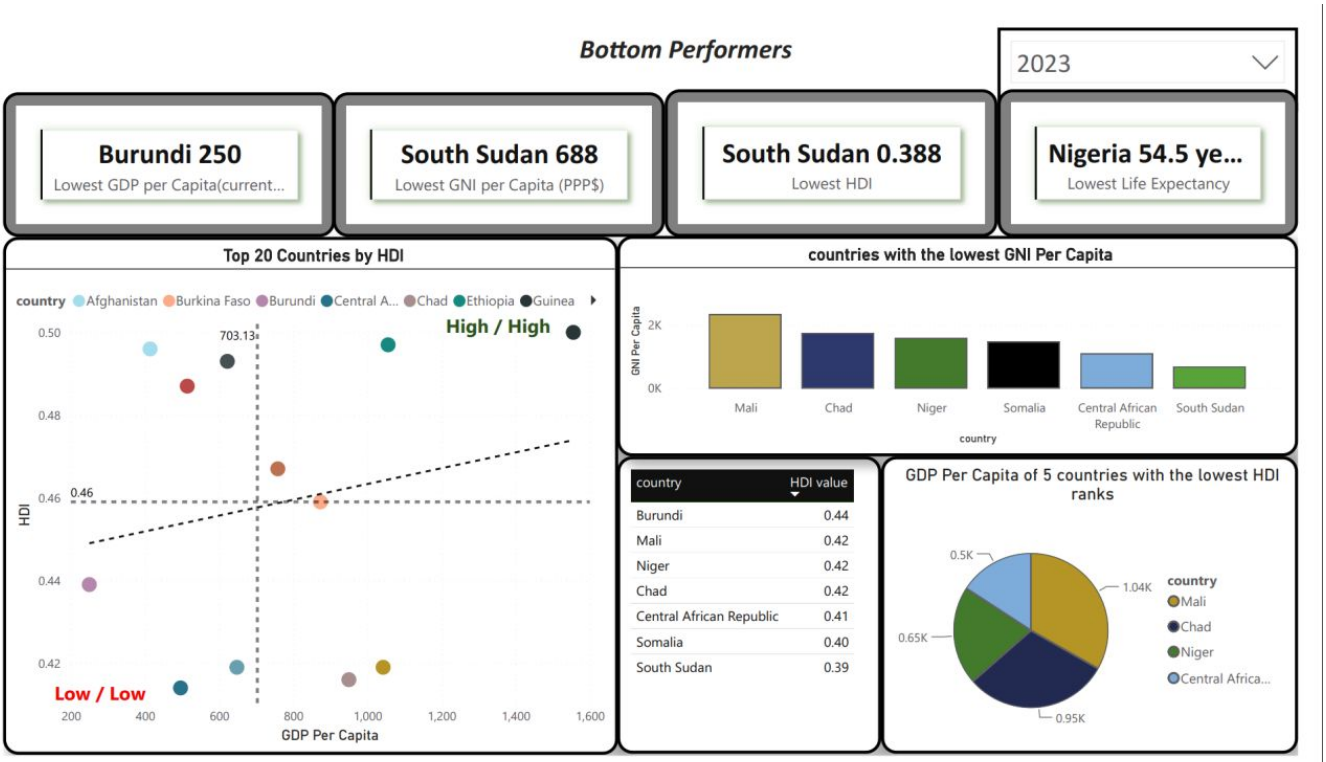

Figure 2: Bottom performers: selected low GDP-per-capita, GNI-per-capita, HDI, and life-expectancy values.

This view applies a similar comparison approach to countries appearing at the lower end of selected indicators. It places income and human-development measures alongside one another, making it easier to see that economic constraints and social outcomes can occur together, while still remaining distinct dimensions of development.

The chart is a descriptive comparison, not an explanation of why a country has a particular outcome. Country values may also be affected by data availability and the year associated with each indicator, so direct comparisons should be made using consistent definitions and periods wherever possible.

Switzerland: economic and human-development profile

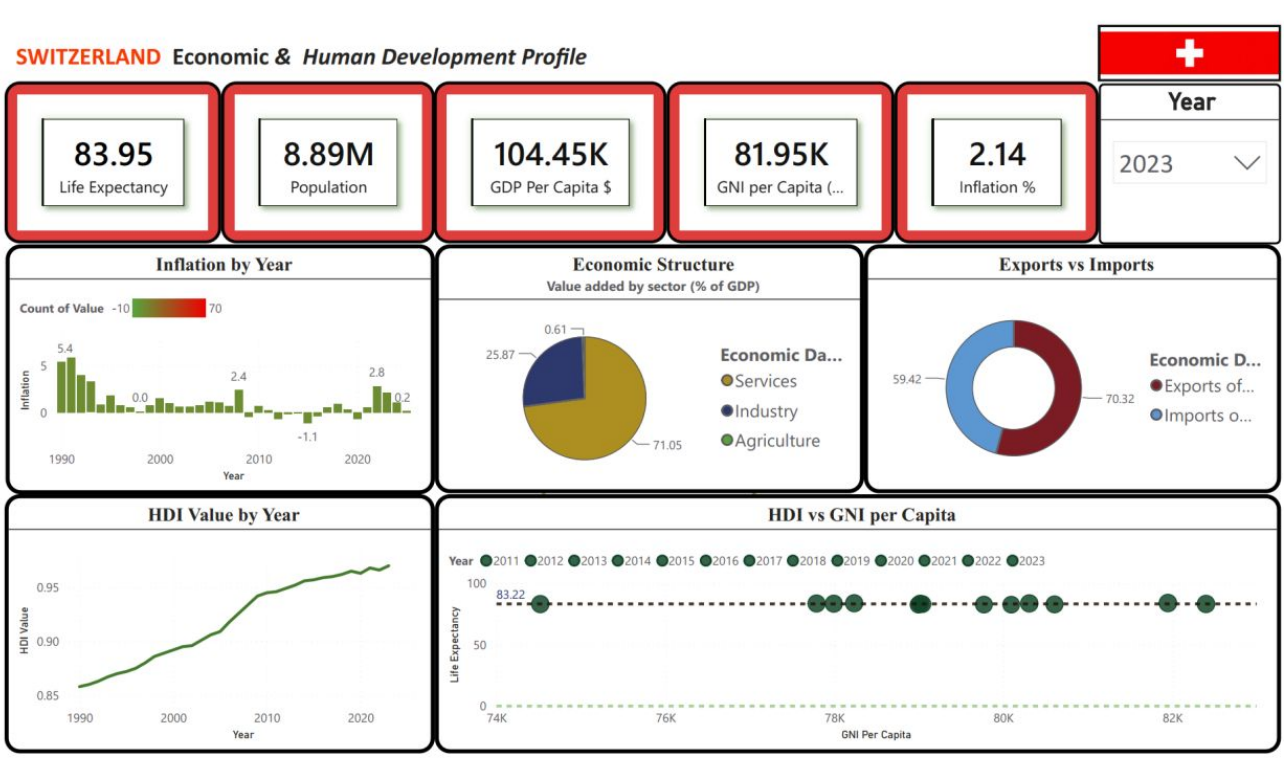

Figure 3: Switzerland profile: headline indicators, inflation, economic structure, trade, and HDI trends.

The Switzerland profile combines headline indicators—including life expectancy, population, GDP per capita, GNI per capita, and inflation—with views of inflation over time, economic structure, exports and imports, and HDI-related trends. This makes the profile broader than a GDP-only snapshot.

The dashboard supports a descriptive assessment of how income, prices, economic composition, trade, and human development appear together for the selected year. It does not by itself establish that any one indicator causes another; the time-series and cross-indicator views are best treated as complementary evidence.

Iceland: economic and human-development profile

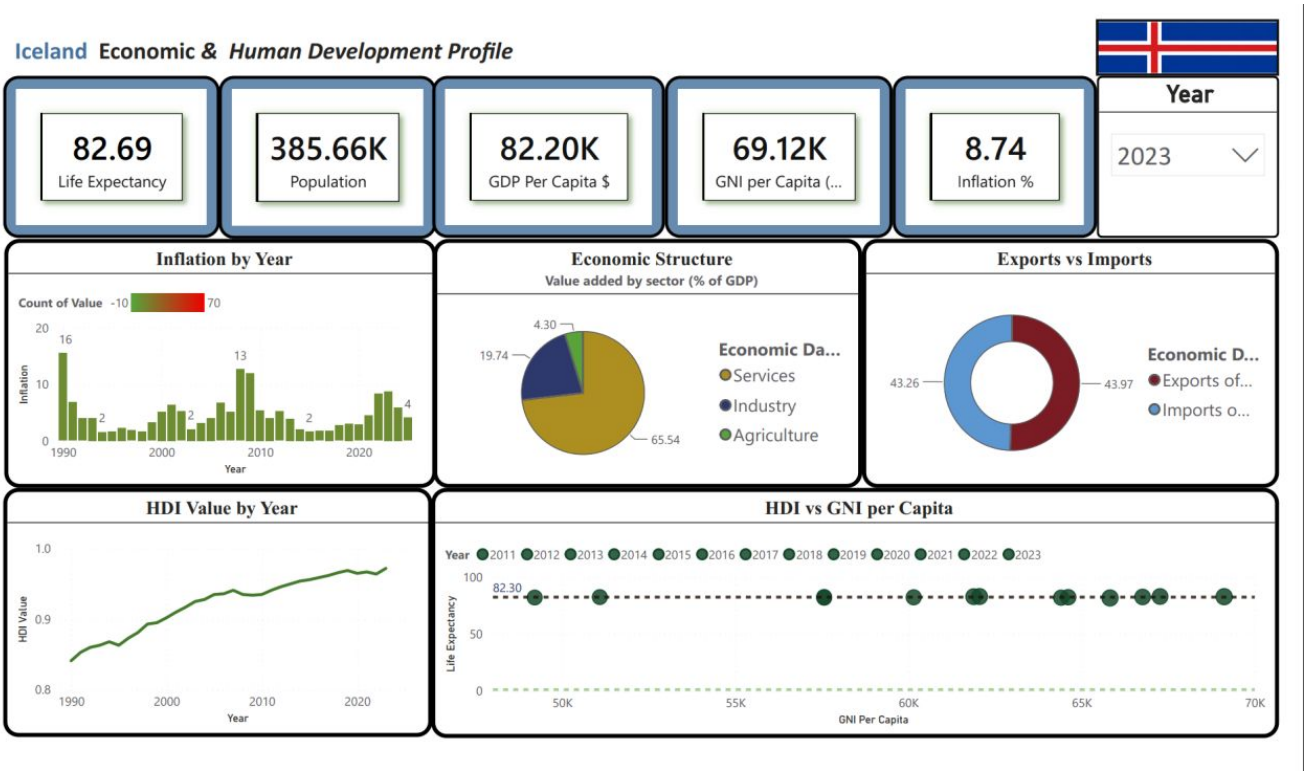

Figure 4: Iceland profile: headline indicators, inflation, economic structure, trade, and HDI trends.

The Iceland profile uses the same visual structure as the Switzerland profile, allowing a more consistent country-to-country comparison. It combines income and population measures with inflation, sector composition, trade, and HDI-related indicators.

Using a shared dashboard layout helps reduce the risk of comparing unlike measures. Differences between the two profiles should nevertheless be interpreted in the context of each indicator's scale, year, and definition, rather than assuming that one country performs uniformly better across all dimensions.

Norway: economic and human-development profile

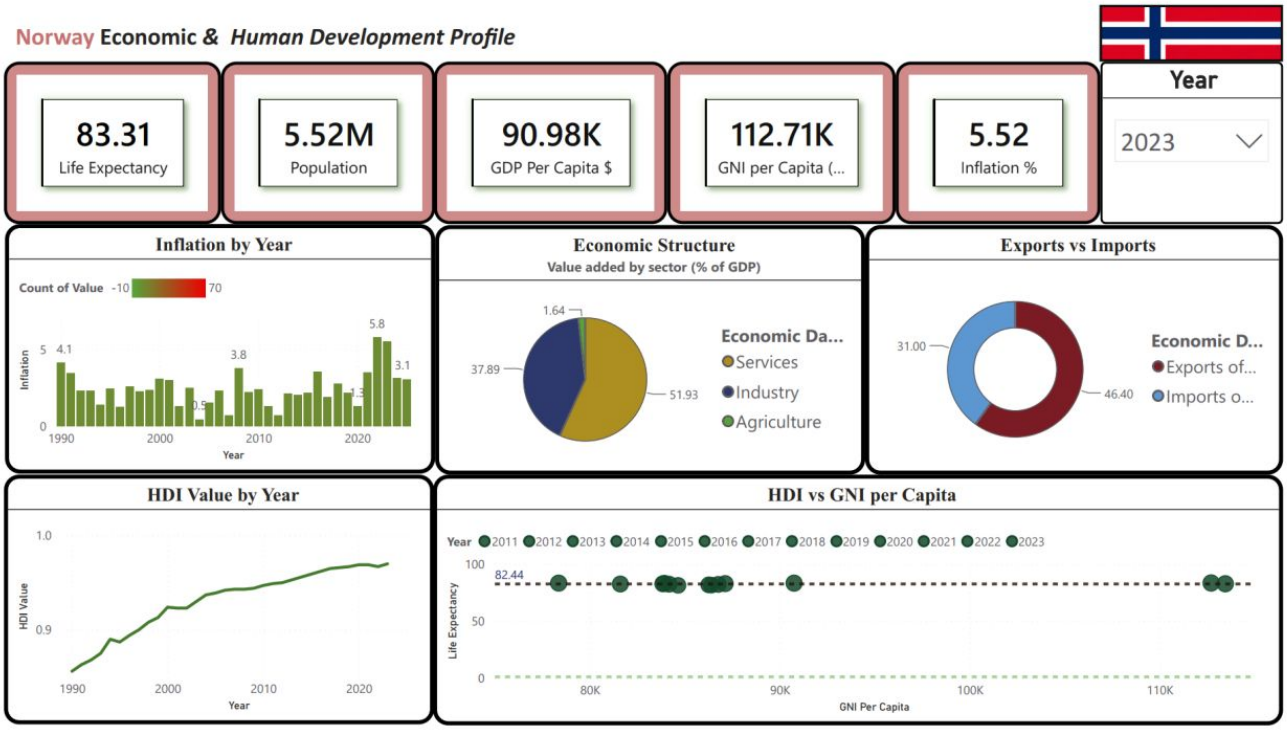

Figure 5: Norway profile: headline indicators, inflation, economic structure, trade, and HDI trends.

Norway's profile brings together living-standard proxies, population, inflation, economic structure, trade, and human-development trends. The separate visuals make it possible to examine economic composition alongside social outcomes instead of treating national income as a complete measure of development.

This profile also provides context for the later natural-resource comparison. The presence of resource-related economic activity is only one part of the picture; the broader development assessment also considers indicators related to income, health, and access to essential services.

Nigeria: economic and human-development profile

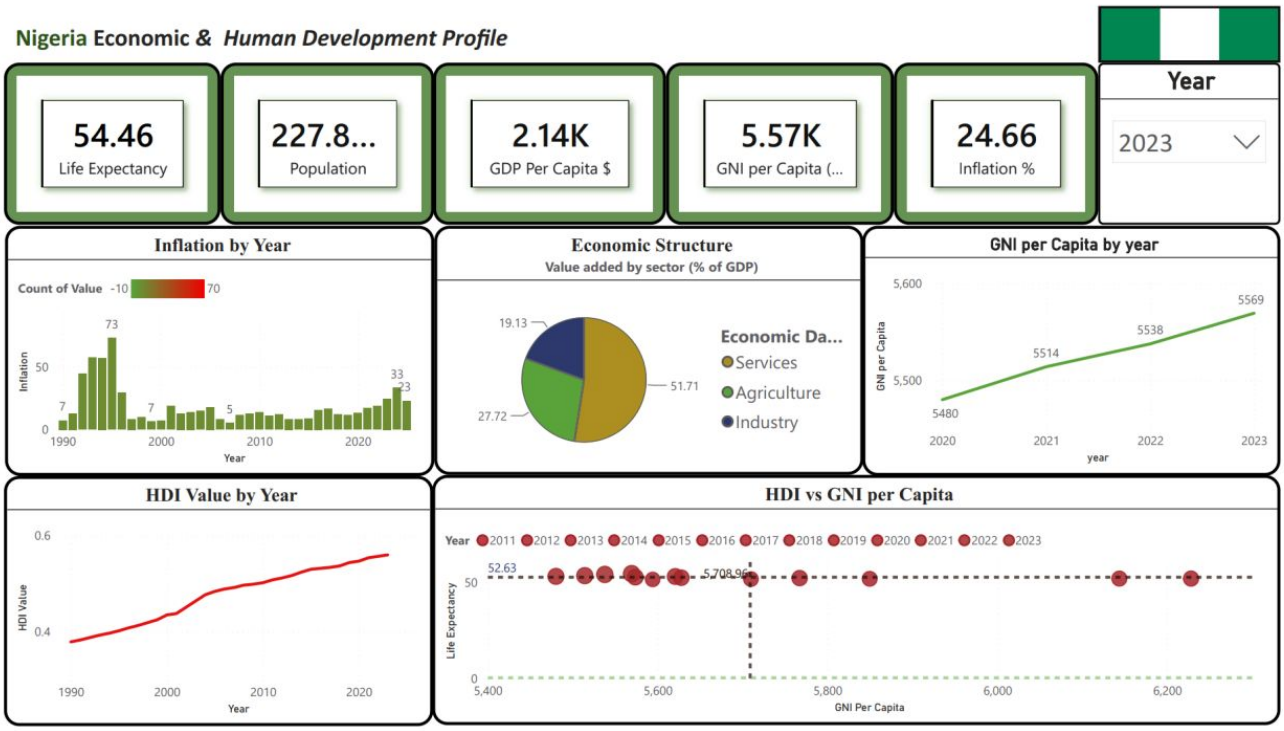

Figure 6: Nigeria profile: headline indicators, inflation, economic structure, GNI per capita, and HDI trends.

The Nigeria profile displays the same core categories used for the other country profiles. Its headline indicators and trend visuals create a basis for comparing economic performance and human-development outcomes with those of Norway and other selected countries.

The dashboard encourages a multi-indicator reading: income measures, inflation, sector composition, and HDI trends answer different questions. Any conclusion about national development should consider these indicators together and avoid treating a single value as a sufficient summary.

Chad: economic and human-development profile

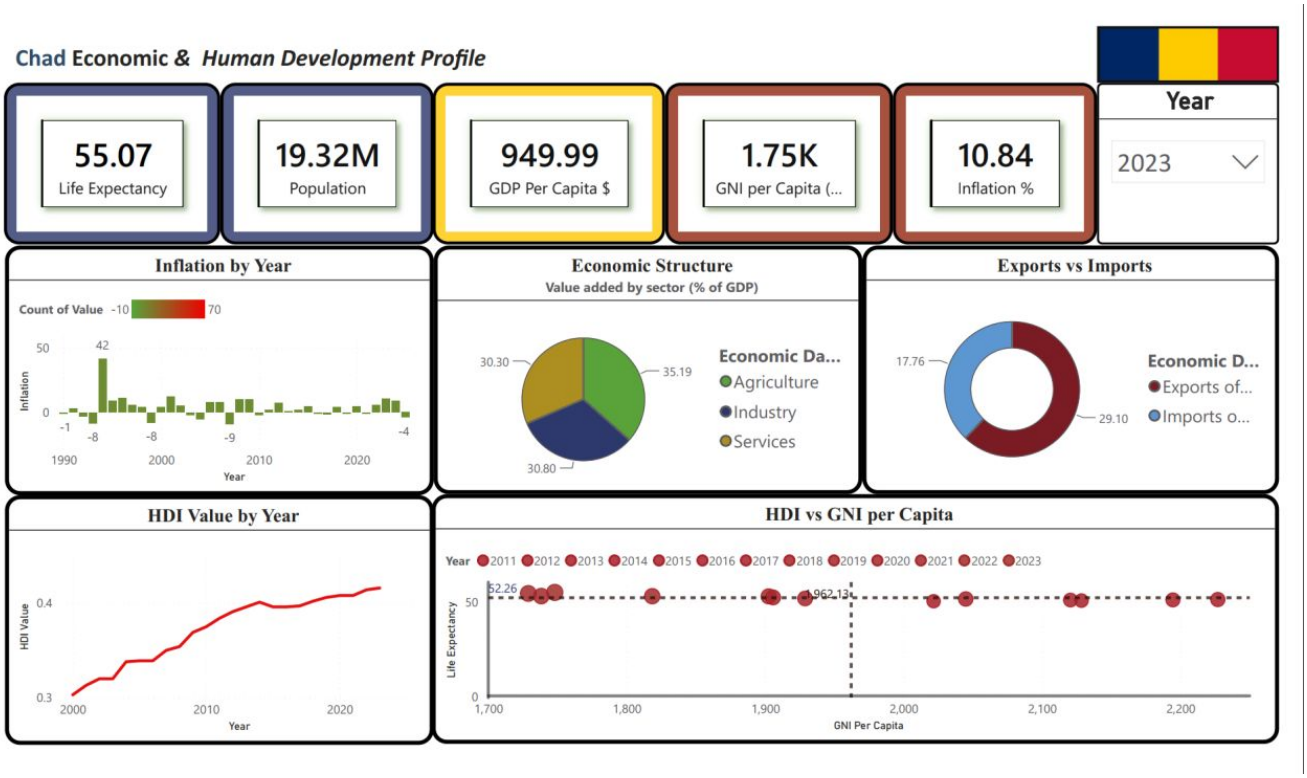

Figure 7: Chad profile: headline indicators, inflation, economic structure, trade, and HDI trends.

The Chad profile provides another comparison point across income, longevity, population, inflation, economic structure, and HDI-related measures. Read alongside the profiles of Switzerland, Iceland, Norway, and Nigeria, it helps illustrate why the project uses a portfolio of indicators rather than a single headline statistic.

The visualizations are descriptive. They identify patterns and differences to investigate further, but they do not explain the institutional, historical, geographic, or policy factors behind those patterns.

Does low inflation mean a strong economy? Switzerland and Chad

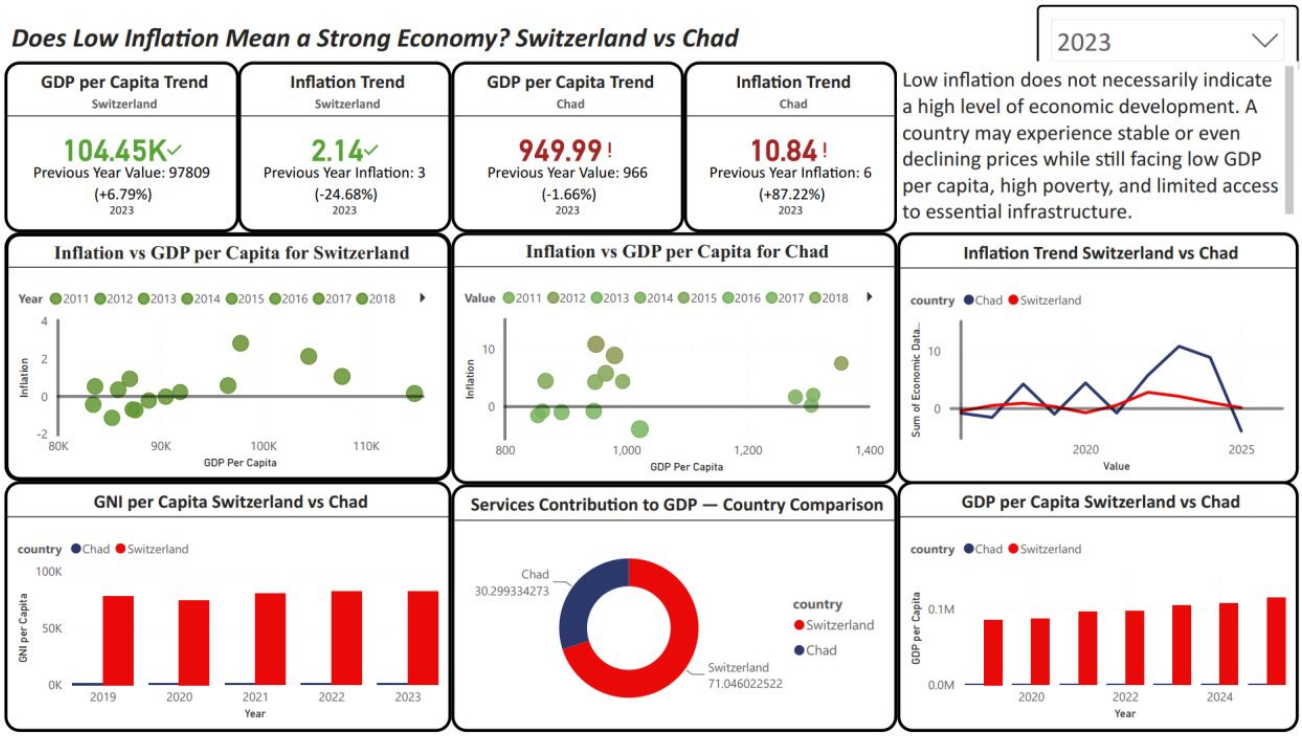

Figure 8: Switzerland and Chad: inflation alongside GDP per capita and other comparative indicators.

This dashboard addresses a central question of the project: does low inflation, by itself, indicate a strong economy or a high level of development? The comparison places inflation trends next to GDP-per-capita measures and additional country-level indicators. The visible contrast illustrates why inflation should be interpreted as one dimension of macroeconomic conditions, not as a standalone development score.

A low inflation rate does not automatically imply high income, strong infrastructure, or better human-development outcomes. Conversely, inflation alone cannot describe the full economic situation. A sound comparison therefore considers price changes together with income, public services, and other indicators, while accounting for the years and definitions used.

Beyond GDP: access to infrastructure and human development

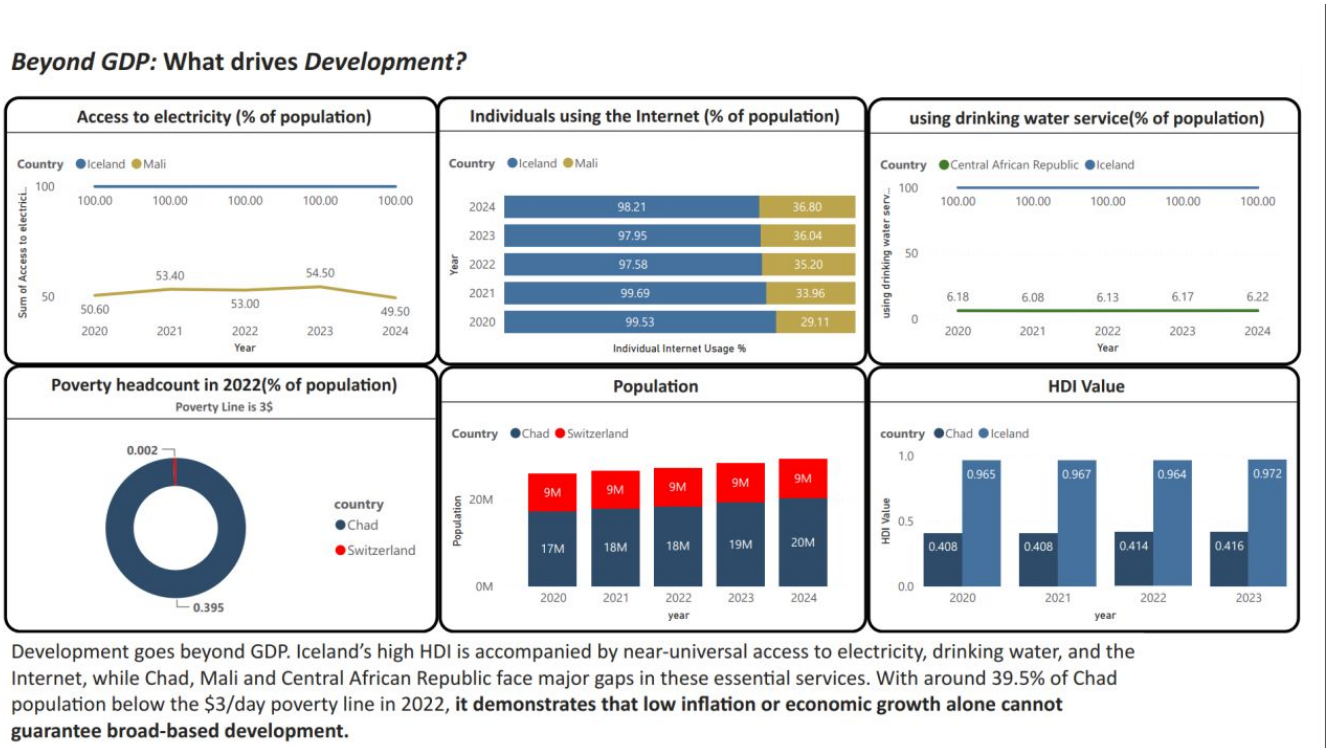

Figure 9: Beyond GDP: access to electricity, internet, clean cooking, poverty, population, and HDI.

This view broadens the analysis beyond income measures by including access to electricity, internet use, and clean cooking technologies, alongside poverty, population, and HDI-related indicators. These measures help connect national economic statistics to aspects of daily living conditions and access to essential infrastructure.

The dashboard's main analytical contribution is to show why development cannot be assessed using GDP alone. Infrastructure access and poverty measures add important context to income and human-development indicators. The comparisons are descriptive, and differences in data coverage or reference years should be checked before drawing precise conclusions.

Does natural-resource wealth guarantee development? Norway and Nigeria

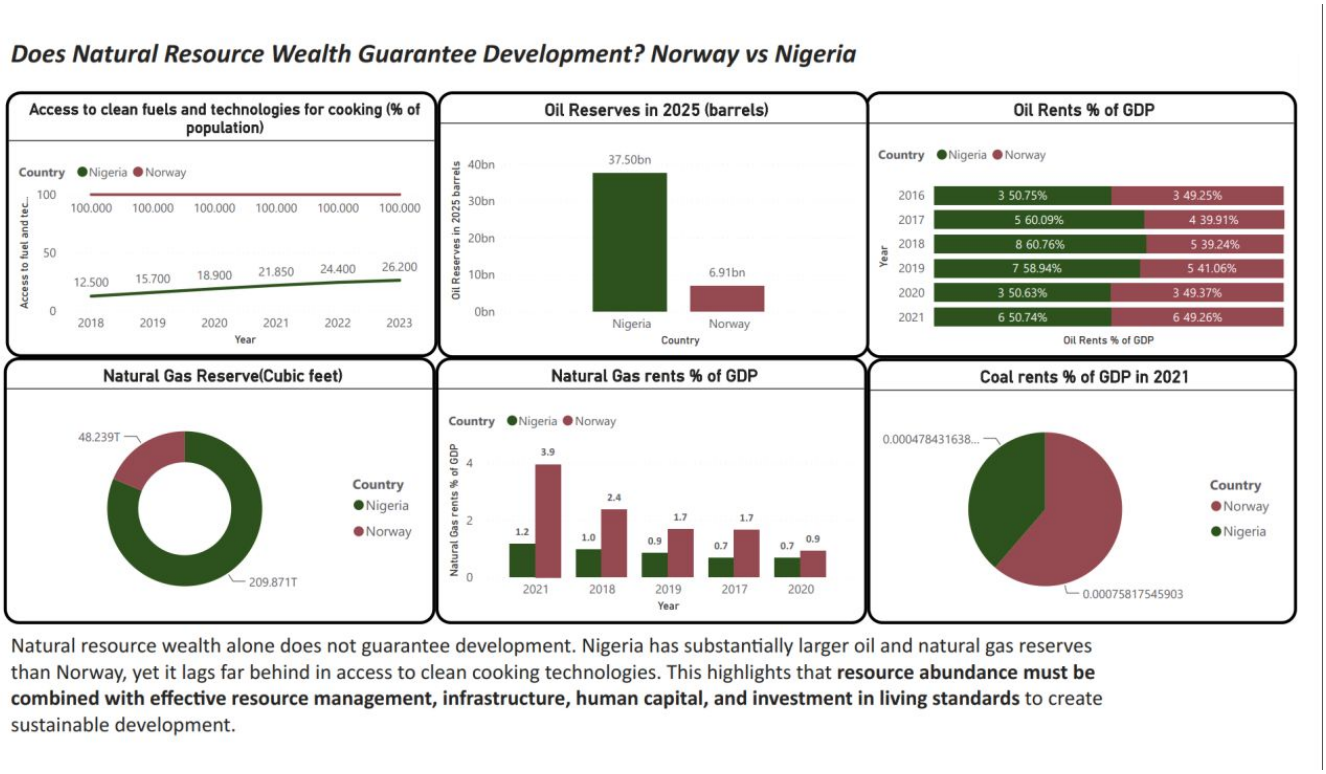

Figure 10: Norway and Nigeria: access to clean cooking, oil and gas reserves, and resource rents.

This comparison considers natural-resource endowments and resource-related rents alongside access to clean cooking technologies. The dashboard distinguishes between the presence of oil and gas resources and the broader development conditions experienced by the population. This distinction is important because resource reserves or resource rents alone do not measure how broadly economic benefits translate into living standards.

The visual supports the project's broader question about resource management: natural-resource wealth does not automatically guarantee inclusive development. Infrastructure, public institutions, investment in human capital, and the distribution and use of resource revenues are relevant contextual factors, although this dashboard alone cannot establish their causal effects. The resource indicators shown also refer to specific reporting years, which should be kept in mind when comparing them with other measures.

Interpretation note: This document summarizes the supplied dashboard visuals. Indicator values and reporting periods should be verified against the original data sources before being used in formal quantitative claims. The charts are descriptive and do not establish causal relationships.
